## Notation

Symbol	Explanation				
n	Number of links/edges in the graph				
$x \in \mathbb{R}^n$	A vector denoting the amount of				
	additional capacity for each link $j$				
т	The number of point-to-point pairs				
	served by the network				
$\tilde{a} \subset \mathbb{D}^m$	A r.v. that represents the demands				
$u \in \mathbb{R}$	for the <i>m</i> point-to-point pairs				
b	Total capacity in the system

# Model Summary (Level 1)

Using this notation, we formulate the initial problem in the following way:

 $\min_{x} \mathbb{E}[h(x, \tilde{d})],$ 

subject to

$$\sum_{j=1}^n x_j \leqslant b,$$
$$x \ge 0.$$

Python Implementation

Optimality Gap

Model Risk

## Model Summary (Level 2)

Within the first level of the model we must optimise the following linear programme:

$$h(x,d) = \min_{s,f} \sum_{i=1}^m s_i,$$

subject to

$$\sum_{i} \sum_{r \in R(i)} A_{ir} f_{ir} \leq x + e,$$
$$\sum_{r \in R(i)} f_{ir} + s_i = d_i,$$
$$f_{ir}, s_i \ge 0,$$

for all  $i \in \{1, \ldots, m\}$  and  $r \in R(i)$ .

#### Deterministic Equivalent Form

We can solve the previous problem as a single linear programme by converting the problem into Deterministic Equivalent form over T scenarios, each with probability  $p^{(t)}$ :

$$\min_{\mathbf{x},s,f} \left\{ \sum_{t=1}^{T} p^{(t)} \left( \sum_{i=1}^{m} s_{i}^{(t)} \right) \right\}$$

subject to

$$\sum_{i=1}^{m} \sum_{r \in R(i)} A_{ir} f_{ir}^{(t)} \leq x + e, \qquad \sum_{j=1}^{n} x_j \leq b,$$
$$\sum_{r \in R(i)} f_{ir}^{(t)} + s_i^{(t)} = d_i^{(t)}, \qquad x, f, s \geq 0,$$

for all  $i \in \{1, ..., m\}$ ,  $t \in \{1, ..., T\}$ .

## Python Implementation

Using the previous formulation allows the problem to be minimised using a single optimisation over the three variables x, s, f.

We chose  $p^{(t)} = 1/T$  as we have no prior information on the likelihood of individual scenarios.

Conditional on the number of scenarios T, the number of constraints is T(n + m) + 1 (excluding non-negativity).

Increasing the number of scenarios reduces the variability within the model, at the cost of increased time complexity. The increase in time taken will limit our computational capabilities going forward.

## Optimality Gap

We find some feasible value of x using a large value of T',

$$\tilde{x} = \left\{ x \in \mathcal{X} : \min_{x,s,f} \frac{1}{T'} \sum_{t=1}^{T'} h(x, \tilde{\xi}) \right\}.$$

Python Implementation

#### Optimality Gap

We find some feasible value of x using a large value of T',

$$\tilde{x} = \left\{ x \in \mathcal{X} : \min_{x,s,f} \frac{1}{T'} \sum_{t=1}^{T'} h(x, \tilde{\xi}) \right\}$$

Then optimality gap is defined as

$$G_{T}^{i} = \frac{1}{T} \sum_{t=1}^{T} h(\tilde{x}, \xi_{it}) - \min_{x,s,f} \frac{1}{T} \sum_{t=1}^{T} h(x, \xi_{it}).$$

Python Implementation 00 Optimality Gap

Model Risk

#### Optimality Gap Results

For sufficiently large T, we know that over k macroreplications

$$\frac{\bar{G}_{T} - \mathbb{E}\left(G_{T}\right)}{\frac{\sigma_{T}}{\sqrt{k}}} \sim t_{k-1},$$

where

$$ar{G}_T = rac{1}{k} \sum_{i=1}^k G_T^k,$$
 $\sigma_T^2 = rac{1}{k-1} \sum_{i=1}^k (G_T^i - ar{G}_T)^2.$

#### Optimality Gap Results

For sufficiently large T, we know that over k macroreplications

$$\frac{\bar{G}_{T} - \mathbb{E}(G_{T})}{\frac{\sigma_{T}}{\sqrt{k}}} \sim t_{k-1},$$

where

$$ar{G}_{T} = rac{1}{k} \sum_{i=1}^{k} G_{T}^{k},$$
 $\sigma_{T}^{2} = rac{1}{k-1} \sum_{i=1}^{k} (G_{T}^{i} - ar{G}_{T})^{2}.$ 

This means we can calculate a one-sided confidence interval for  $\mathbb{E}(G_T)$ :

$$\left(0, \bar{G}_T + t_{k-1,\alpha} \frac{\sigma_T}{\sqrt{k}}\right).$$

#### Risk reduction methods

Possible methods to make the formulation more risk averse:

- 1. VaR.
- 2. CVaR
- 3. Minimise Variance.
- 4. Minimise Semivariance.
- 5. Minimise the squared losses.
- 6. More recent proposals e.g. most probable maximum size of risk events (MPMR) [Chen and Cheng (2022)]

$$\beta$$
-CVaR

 $\beta\text{-}\mathsf{CVaR}$  is defined as

$$\beta$$
-CVaR $(\theta) = \int_{\beta}^{1} F^{-1}(u) du$ 

which can be thought of as the expected loss if the worst case threshold is every passed.

## Minimising $\beta$ -CVaR

We previously estimated min  $\mathbb{E}(h(x,\xi))$  by

$$\min_{x,s,f}\left\{\sum_{t=1}^T \frac{1}{T}h(x,\xi)^{(t)}\right\}.$$

By a theorem from Rockafellar and Uryasev (2002) we have

$$\min \beta$$
-CVaR =  $\min \left( \alpha + \frac{1}{1-\beta} \mathbb{E} \left( h(x,\xi) - \alpha \right)_+ \right) \right),$ 

Python Implementation

Optimality Gap

Model Risk 000€00 References 0

## Minimising $\beta$ -CVaR

We previously estimated min  $\mathbb{E}(h(x,\xi))$  by

$$\min_{x,s,f}\left\{\sum_{t=1}^T \frac{1}{T}h(x,\xi)^{(t)}\right\}.$$

By a theorem from Rockafellar and Uryasev (2002) we have

$$\min \beta - \mathsf{CVaR} = \min \left( \alpha + \frac{1}{1 - \beta} \mathbb{E} \left( h(x, \xi) - \alpha \right)_+ \right) \right),$$

and so we can similarly estimate min  $\beta$ -CVaR by

$$\min_{\alpha,x,s,f} \left\{ \alpha + \frac{1}{1-\beta} \sum_{t=1}^{T} \frac{1}{T} \left( h(x,\xi)^{(t)} - \alpha \right)_{+} \right\}.$$

#### Auxiliary Variables

Python cannot compute the minimum of a maximum, so we introduce a new variable z, a vector of length T. We then implement

$$\min_{\alpha,x,s,f,z} \left\{ \alpha + \frac{1}{1-\beta} \sum_{t=1}^{T} \frac{1}{T} z^{(t)} \right\},\,$$

with additional constraints

$$z^{(t)} \ge h(x,\xi)^{(t)} - \alpha,$$
  
$$z^{(t)} \ge 0,$$

for all  $t \in \{1, ..., T\}$ .
