Daniel Waller

## What are multiple seasonalities?

- Time series are often broken down into three components:
  - Trend the rate of increase/decrease of the series.
  - Seasonality a pattern which repeats regularly over a fixed period.
  - Error a random quantity.
- Implicit assumption that there is only one seasonal pattern.
- Holt-Winters exponential smoothing based on this assumption, as are many other base forecasting methods.

#### Daniel Waller

Lancaster University

## What are multiple seasonalities?

- Sometimes there is clearly more than one seasonal influence on the time series.
- For instance, half-hour of day and half-hour of week both have a seasonal effect on the demand of electricity in the series below.

#### Daniel Waller

Exponential-smoothing based approaches in the literature:

- Double/triple seasonal ES (Taylor 2003, 2010).
- Intraday ES (Gould 2008)
- TBATS (De Livera et al. 2011)
- Parsimonious ES (Taylor and Snyder 2012).

Main motivation has been short-term load forecasting for electricity (other utilities as well).

イロト イボト イヨト イヨト

## A new motivation - retail

Demand in retail may be subject to multiple seasonal influences:

- Can we use multiple seasonal techniques?
- What adaptations need to be made?

Retail forecasting differs from short-term electricity load forecasting in a few respects:

- Exogenous variables (price, promotions, etc.)
- Substitutable/complementary product effects.
- More hierarchies/levels to forecast.

イロト イポト イヨト イヨト

## Double-seasonal ES

# Adaptation of Taylor (2003) to single-seasonal ES. Additive version:

$$\begin{array}{lll} \text{Level:} & l_t = \alpha(y_t - s_{t-m_1} - d_{t-m_2}) + (1 - \alpha)(l_{t-1} + b_{t-1}) \\ \text{Trend:} & b_t = \beta(l_t - l_{t-1}) + (1 - \beta)b_{t-1} \\ \text{Seas 1:} & s_t = \gamma(y_t - l_{t-1} - b_{t-1} - d_{t-m_2}) + (1 - \gamma)s_{t-m_1} \\ \text{Seas 2:} & d_t = \delta(y_t - l_{t-1} - b_{t-1} - s_{t-m_1}) + (1 - \delta)d_{t-m_2} \end{array}$$

with forecasting equation:

$$\hat{y}_{t+1} = l_t + b_t + s_{t+1-m_1} + d_{t+1-m_2} + \phi(y_t - l_{t-1} - b_{t-1} - s_{t-m_1} - d_{t-m_2})$$
  
for a horizon of 1.

#### Daniel Waller

## Double-seasonal ES

Adaptation of Taylor(2003) to single-seasonal ES. Multiplicative version:

Level:	$l_t = \alpha \frac{y_t}{s_{t-m_1}d_{t-m_2}} + (1-\alpha)(l_{t-1}+b_{t-1})$
Trend:	$b_t = \beta(l_t - l_{t-1}) + (1 - \beta)b_{t-1}$
Seas 1:	$s_t = \gamma \frac{y_t}{l_t d_{t-m_2}} + (1-\gamma)s_{t-m_1}$
Seas 2:	$d_t = \delta \frac{y_t}{l_t s_{t-m_1}} + (1-\delta)d_{t-m_2}$

with forecasting equation:

$$\hat{y}_{t+1} = (l_t + b_t)s_{t+1-m_1}d_{t+1-m_2} + \phi(y_t - (l_{t-1} + b_{t-1})s_{t-m_1}d_{t-m_2})$$
for a horizon of 1.

## Parsimonious ES

Proposed by Taylor and Snyder (2012), building on the work of Gould (2008):

$$\begin{split} e_t &= y_t - \sum_{i=1}^M I_{it} s_{i,t-1} \\ s_{it} &= s_{i,t-1} + (\alpha + \omega I_{it}) e_t \qquad \text{i} = 1,2,\dots,\text{M} \\ I_{it} &= \begin{cases} 1 \text{ if period t occurs in season i} \\ 0 \text{ otherwise} \end{cases} \end{split}$$

with forecasting equation:

$$\hat{y}_{t+1} = \sum_{i=1}^{M} I_{i,(t+1)} s_{i,t} + \phi e_t$$

イロト イボト イヨト イヨト

Daniel Waller

## Parsimonious ES

### Advantages

- Allows unconstrained clustering of periods.
- Fewer number of initial terms to estimate.

### **Limitations**

- Cannot incorporate exogenous information.
- Clustering of seasons non-automatic/non-scalable.

イロト イポト イヨト イヨト

Daniel Waller

## Empirical testing

We use the example of fuel - below is a plot of demand:

- Daily totals
- Aggregated over a sample of retail sites

Modelling multiple seasonalities across hierarchical aggregation levels

## Empirical setup

- Comparing three methods:
  - Single-seasonal ES (benchmark)
  - Double-seasonal ES
  - Parsimonious ES
- Estimation: 1st 2 years (730 obs.)
- Holdout: Last year (365 obs.)
- Horizon Up to 21 days

イロト イポト イヨト イヨト

Daniel Waller

## **PES Model Selection**

23 seasons:

- 14 seasons around Christmas
- 2 seasons around Easter
- 7 seasons for 'normal' day of week

	Univariate testing	
Results		

MAPE for one-step-ahead forecasts:

Table: Excluding Christmas/Easter

	MAPE	MAE
PES	3.33%	936,422
DSHW	4.79%	1,388,141
ES	3.95%	1,131,649

Table: Christmas/Easter only

	MAPE	MAE
PES	14.28%	3,286,438
DSHW	8.80%	1,800,825
EC	26 200/	1 008 516

Image: A mathematical states and a mathem

-

## Accuracy vs. Horizon

# Graph shows overall MAPE against horizons of up to 21 observations.

Daniel Waller

## Multivariate testing

Compare univariate results to 2 regression models:

- Seasonal dummies only.
- Inclusion of exogenous information:
  - Price
  - Weather vars x11
- Use naïve for future values of exogenous predictors.

Daniel Waller

Lancaster University

イロト イポト イヨト イヨト

	Models	Multivariate testing
<b>D</b>		
Results		

- PES best at short horizons.
- Regression is robust at long horizons.

## Conclusions

- Multi-seasonal methods may hold promise in retail.
- Univariate PES is most accurate at short horizons.
- Longer horizons/short data histories potentially problematic.

Research Plan

- Extension of PES to multivariate case.
- Scalable/automatic approach to season clustering.
- Multiple series/hierarchies.
